**Important User Information**

The products and application data described in this manual are useful in a wide variety of different applications. Therefore, the user and others responsible for applying these products described herein are responsible for determining the acceptability for each application. While efforts have been made to provide accurate information within this manual, AMCI assumes no responsibility for the application or the completeness of the information contained herein.

UNDER NO CIRCUMSTANCES WILL ADVANCED MICRO CONTROLS, INC. BE RESPONSIBLE OR LIABLE FOR ANY DAMAGES OR LOSSES, INCLUDING INDIRECT OR CONSEQUENTIAL DAMAGES OR LOSSES, ARISING FROM THE USE OF ANY INFORMATION CONTAINED WITHIN THIS MANUAL, OR THE USE OF ANY PRODUCTS OR SERVICES REFERENCED HEREIN.

No patent liability is assumed by AMCI, with respect to use of information, circuits, equipment, or software described in this manual.

The information contained within this manual is subject to change without notice.

This manual is copyright 2018 by Advanced Micro Controls Inc. You may reproduce this manual, in whole or in part, for your personal use, provided that this copyright notice is included. You may distribute copies of this complete manual in electronic format provided that they are unaltered from the version posted by Advanced Micro Controls Inc. on our official website: www.amci.com. You may incorporate portions of this documents in other literature for your own personal use provided that you include the notice “Portions of this document copyright 2018 by Advanced Micro Controls Inc.” You may not alter the contents of this document or charge a fee for reproducing or distributing it.

**Standard Warranty**

ADVANCED MICRO CONTROLS, INC. warrants that all equipment manufactured by it will be free from defects, under normal use, in materials and workmanship for a period of [18] months. Within this warranty period, AMCI shall, at its option, repair or replace, free of charge, any equipment covered by this warranty which is returned, shipping charges prepaid, within eighteen months from date of invoice, and which upon examination proves to be defective in material or workmanship and not caused by accident, misuse, neglect, alteration, improper installation or improper testing.

The provisions of the "STANDARD WARRANTY" are the sole obligations of AMCI and excludes all other warranties expressed or implied. In no event shall AMCI be liable for incidental or consequential damages or for delay in performance of this warranty.

**Returns Policy**

All equipment being returned to AMCI for repair or replacement, regardless of warranty status, must have a Return Merchandise Authorization number issued by AMCI. Call (860) 585-1254 with the model number and serial number (if applicable) along with a description of the problem during regular business hours, Monday through Friday, 8AM - 5PM Eastern. An "RMA" number will be issued. Equipment must be shipped to AMCI with transportation charges prepaid. Title and risk of loss or damage remains with the customer until shipment is received by AMCI.

**24 Hour Technical Support Number**

24 Hour technical support is available on this product. If you have internet access, start at www.amci.com. Product documentation and FAQ’s are available on the site that answer most common questions.

If you require additional technical support, call (860) 583-1254. Your call will be answered by the factory during regular business hours, Monday through Friday, 8AM - 5PM Eastern. During non-business hours an automated system will ask you to enter the telephone number you can be reached at. Please remember to include your area code. The system will page an engineer on call. Please have your product model number and a description of the problem ready before you call.

**Waste Electrical and Electronic Equipment (WEEE)**

At the end of life, this equipment should be collected separately from any unsorted municipal waste.

ABOUT THIS MANUAL

Read this chapter to learn how to navigate through this manual and familiarize yourself with the conventions used in it. The last section of this chapter highlights the manual’s remaining chapters and their target audience.

Audience

This manual explains the installation and operation of AMCI’s absolute digital output DuraCoders. It is written for the engineer responsible for incorporating the Absolute Digital DuraCoder into a design as well as the engineer or technician responsible for its actual installation. If there are any unanswered questions after reading this manual, call the factory. An applications engineer will be available to assist you.

Navigating this Manual

This manual is designed to be used in both printed and on-line forms. Its on-line form is a PDF document, which requires Adobe Acrobat Reader version 7.0+ to open it. You are allowed add notes and annotations as well as select and copy sections for use in other documents. If you decide to print out this manual, all sections contain an even number of pages which allows you to easily print out a single chapter on a duplex (two-sided) printer.

Manual Conventions

Three icons are used to highlight important information in the manual:

- **NOTES** highlight important concepts, decisions you must make, or the implications of those decisions.
- **CAUTIONS** tell you when equipment may be damaged if the procedure is not followed properly.
- **WARNINGS** tell you when people may be hurt or equipment may be damaged if the procedure is not followed properly.

The following table shows the text formatting conventions:

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>

**Absolute Digital DuraCoder Overview**

DuraCoders are designed as direct replacements for optical encoders. Instead of being designed around a disk and optics, a DuraCoder uses a resolver as its primary shaft position sensor. Constructed in a manner similar to high precision motors, resolvers are absolute, single turn position sensors that are unsurpassed in terms of ruggedness and reliability. The resolver is an analog device whose outputs vary sinusoidally as the shaft is rotated. If you are interested in learning more about resolvers, read the article on our website at: [https://www.amci.com/industrial-automation-resources/plc-automation-tutorials/what-resolver/](https://www.amci.com/industrial-automation-resources/plc-automation-tutorials/what-resolver/).

The resolver’s analog signals are decoded into a 12 bit position value by electronics incorporated into the DuraCoder. This 12 bit (4096 count), absolute position value is available as a parallel digital output. Several different output codes and voltage level outputs are available.

In addition to the actual position outputs, the Absolute Digital DuraCoders also offer two inputs that control the outputs. The Latch Input is used to control when the position values update and the Direction Input controls the direction of rotation needed to produce increasing counts.

The Absolute Digital DuraCoder is available in a variety of industry standard size 25 optical encoder packages. A flange mount unit with a 3/8" shaft and a side connector is shown in figure R1.1. Servo mount and end connect units are also available. If your application requires you to mount the DuraCoder to a motor, a blind shaft mounting option is available as well. Finally, a face mount unit with a 5/8 inch shaft is available for applications that may be exposed to high shaft loads.

Outline drawings of all of the packing options is available in the *Outline Drawings* section of the *Installation* chapter, starting on page 11.

**Absolute Digital DuraCoder Diagnostics**

Starting in August of 2018, Absolute Digital DuraCoders include additional diagnostic features.

- **Fault Output** - This output is active during normal operation and goes inactive when one or more of the following conditions exists:
  1) Over temperature of the output drivers
  2) Output shorted to ground
  3) Output shorted to Vdc
  4) Open connection or wire.

- **Test Input** - Used to test the outputs of the unit. This single input can be used to force all of the outputs into their active or inactive states. A full explanation of the uses of this pin can be found in Task 2, *Diagnostics* starting on page 21.

- **Status LED** - Located on the back of the unit, this LED shows the status of the unit under normal operating conditions, and the status of the outputs when used with the Test Pin.
**Part Numbering System**

**DC25**
- **HOUSING**
  - F = Square Flange
  - S = 2.5" Dia. Servo Mount
  - H = 63mm Blind Shaft Mount
- **SHAFT DIA.**
  - Standard Shaft
    - 1 = 0.375" Dia.
    - 2 = 10mm Dia.
    - 3 = 0.250" Dia.
    - 5 = 0.625" Dia.
- **OUTPUT CODING**
  - 1 = 1,024 Count, Gray Code
  - 2 = 1,024 Count, Binary
  - 3 = 4,096 Count, Gray Code
  - 4 = 4,096 Count, Binary
  - 5 = 360 Count, BCD
  - 6 = 1,000 Count, BCD
- **CONNECTOR**
  - S = Side
  - E = End

**BEARING SEAL**
- B = Nitrile (standard)
- V = Viton

**DURACODER TYPE**
- A = Absolute Parallel, Level Update
- B = Absolute Parallel, Edge Update

**Description of Outputs**

**Output Codecs**

The Absolute Digital DuraCoder can output its data in 12 bit Natural Binary, 12 bit Gray Code, or 12 bit BCD formats. In Natural Binary and Gray Code formats, the maximum output value is 4,095. For BCD format, the maximum output value is 999.

In new installations, the sole advantage of Gray Code over Natural Binary is that only one bit changes per count. This allows you to easily check the validity of the position data. This one bit change holds true only if your number of counts per turn is a power of two. (2, 4, 8, ... 4,096) If your number of counts per turn is not set to a power of two, the transition between your maximum count and zero will result in two or more bits changing in the data.

**Output Update Control**

Position data updates are controlled by a single pin named *Latch Control* and the type of control is set when the DuraCoder is ordered. Two types of position update control are available.

- **Level Sensitive (Part # starts: DC25?-??A)** – The position data updates every 325 microseconds while the Latch Control pin is at a Logic 1 voltage or the pin is left open. The position data will freeze within 25 microseconds of this pin being driven to a Logic 0 voltage. The position data will begin to update within 325 microseconds once it is released from the Logic 0 voltage level. If the Latch Control pin is at a Logic 0 on power up, all outputs will be in their zero state until the first positive transition. Position data will not be valid until this transition.

![Figure R1.3 Level Sensitive Update](image-url)
Description of Outputs (continued)

Output Update Control (continued)

- **Edge Sensitive (Part # starts: DC25-???)** – A Logic 0 → 1 or 1 → 0 transition on the Latch Control input will update the outputs within 325 microseconds. The output will then freeze until another valid transition. Transitions must be a minimum of 325 microseconds apart. (1.5 kHz at a 50% duty cycle maximum.) On power up, all of the outputs will be in their zero state until the first valid transition occurs. Position data will not be valid until this transition.

Output Electrical Configurations

Three different electrical configurations are available for the outputs.

- Open Collector Sourcing
- Open Collector Sinking
- Open Collector Sinking with a 10K\(\Omega\) resistor to +Vin

Full characteristics for the output are available in the *Electrical Specifications* section on the following page. Outputs can be ordered as a High True Output or a Low True Output. The table below shows the states.

<table>
<thead>
<tr>
<th>Open Collector Source Output</th>
<th>Conducts to VIN</th>
<th>High-Impedance</th>
<th>Logic 1</th>
<th>Logic 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open Collector Sink Output</td>
<td>High-Impedance</td>
<td>Conducts to GND</td>
<td>Logic 1</td>
<td>Logic 0</td>
</tr>
<tr>
<td>Sink Output w/ 10 K(\Omega) Pullup</td>
<td>High-Impedance Pulled to VIN through 10 K(\Omega)</td>
<td>Conducts to GND</td>
<td>Logic 1</td>
<td>Logic 0</td>
</tr>
</tbody>
</table>

Status LED

As shown in figure R1.5, the Status LED is located on the back of the unit.

**Normal Operation (Test Pin open)**

- **Steady Green** - The encoder is operating normally without a fault.
- **Steady Red** - One or more of the following fault conditions exists:
  1) Over temperature of the output drivers
  2) Output shorted to ground
  3) Output shorted to Vdc
  4) Open connection or wire.

**Test Mode (Test Pin grounded)**

- **OFF** - The output are acting normally.
- **ON** - A fault condition exists on one or more of the outputs. See Task 2, *Diagnostics* starting on page 21 for information on diagnosing the error condition.
**Electrical Specifications**

**Operating Voltage**
10.8 Vdc to 26.4 Vdc (12 to 24 Vdc nominal)

**Power Requirements**
1.2 W max. (50mA @ 24Vdc)
All outputs in their inactive state.

**Position Resolution**
2 to 4,096 counts with Gray Code or Natural Binary output format.
2 to 1,000 counts with BCD output format

**Position Update Control**
Latch Control pin on connector that is factory set to either Level control or Edge control.
With Level control, the outputs update continuously while pin is at a logic 1 or open circuit. Outputs freeze when input tied to DC Return.
With Edge control, outputs update within 325 microseconds of a transition from logic 0 to logic 1 or logic 1 to logic 0. Transitions must occur at a minimum of 325 microseconds apart. (1.5KHz at 50% duty cycle)

**Logic Level Input Voltages**
Logic 0: 0 Vdc to 0.8 Vdc.
Logic 1: 2 Vdc to Operating Voltage.
Inputs have pull up resistors, so leaving them disconnected will act as a logic “1”

**Position Update Time**
325 microseconds when using Level update control and the Latch Control pin has been at a logic 1 or open circuit for a minimum of 325 microseconds

**Max. Output Settling Time**
325 microseconds. Occurs on either transition when using Edge control or when Latch Control pin changes from Logic 0 to Logic 1 state when using Level control.

**Direction of Increasing Counts**
Default CCW looking at shaft
Can be set to CW increasing by shorting pin R to DC Return.

**Output Types**
Open Collector Sourcing, Open Collector Sinking, and Sinking with 10 KΩ pull-up resistor.

**On State Current**
500 mA per output without damage.

**On State Resistance**
0.75 Ω max. (0.03 Vdc drop across driver at 40 mA)

**Leakage Current**
5 microamps maximum

**Environmental Specifications**

**Operating Temperature**
-40°F to +185°F (-40°C to +85°C)

**Shock**
50g, 11 millisecond duration

**Vibration**
20g, 5 to 2000Hz

**Enclosure Rating**
IP67

**Approximate Weight**
2.0 lbs. (0.91 Kg) 0.625" shafts
1.4 lbs. (0.65 Kg) All other shafts

**Mechanical Specifications**

**Package Style**
2.5 inch aluminum housing with flange, servo, or blind shaft mounting

**Connector Location**
Side or End

**Housing**
Powder coated aluminum

**Shaft**
0.250", 0.375", 0.625", or 10mm
Blind Shaft with 0.375", 0.500", 10mm or 12 mm hole

**Max. Starting Torque @ 25°C**
2.0 oz-in: 0.250", 0.375", and 10mm shafts
6.0 oz-in: All blind shafts
6.0 oz-in: 0.625" shaft

**Moment of Inertia (oz-in-sec²)**
6.00 X 10⁻⁴: 0.250", 0.375", and 10mm shafts
7.00 X 10⁻⁴: All blind shafts
8.50 X 10⁻⁴: 0.625" shaft

**Max. Operating Speed**
6000 RPM

**Max. Shaft Loading (0.625" shaft)**
Axial: 50 lbs. (222 N)
Radial: 100 lbs. (445 N)
As specified max. loads, bearing life is 2X10⁹ revolutions min.

**Max. Shaft Loading (All other shafts)**
Axial: 20 lbs. (89 N)
Radial: 40 lbs. (178 N)
As specified max. loads, bearing life is 2X10⁹ revolutions minimum.

Shaft Loading

Limit shaft loading to the following values. These values statistically yield an L10 life of 2X10^9 revolutions. (L10 life is a rating which means that statistically, only 10% of the bearings will have failed after 2X10^9 revolutions.) Shaft loading has an exponential effect on bearing life. The bearings will statistically last longer if you can limit shaft loading below the given values. Consider using the 5/8" shaft DuraCoder from AMCI if your shaft loading is expected to be greater than the values given below. Outline drawings for the 5/8" shaft DuraCoders start on page 17.

**Shaft Loading**

The load that the Analog DuraCoder presents to your input shaft, which is equal to the load presented to the DuraCoder by your input shaft, is difficult to calculate and is dependent on the accuracy of the mounting. The flexible metal mounting bracket will be able to absorb most of the radial loading forces, but accurate mounting of the DuraCoder is still important.

Connector Pinout

Figure T1.11 shows the pin designations on the MS3112E-14-19P connector. AMCI sells a straight mating connector under the AMCI part number: MS-19.

AMCI does not supply factory made cables for the Absolute Digital DuraCoder because of the many possible configurations.

**Pins A-M: Position Output** – These pins output the absolute position value. Pin A is the least significant bit.

**NOTE** Prior to the August 2018 release of the Absolute Digital DuraCoder, the “N” and “P” pins were “No Connection” pins.

**Pin N: Error Output** – The output state of this pin is active during normal operation. It switches to its inactive state when there is a fault condition. The four detectable fault conditions are:

- Output driver over-temperature
- Output shorted to ground
- Output shorted to Vdc
- Open wire or connections

These faults are latched. Once they occur, the DuraCoder will report the error until it is cleared. There are two methods to clear the error.

1) Cycle power to the DuraCoder
2) Pull the Test input low for a minimum of 10 milliseconds and release it.

If the fault condition no longer exists, the Error output will return to its active and the Status LED on the back of the unit will change from red to green.

See table T2.2, *Output Voltage States*, found on page 21 for the output voltage levels when the output is active or inactive.

**Pin P: Test Input** – This pin is used to test the outputs of the DuraCoder and clear fault conditions. This pin should be left open for normal operation. Connecting this pin to GND will place the DuraCoder in test mode. The use of this pin is fully described in Task 2, *Diagnostics*, starting on page 21.

**Connector Pinout**

**Pin R: Direction Control** – This pin controls which direction the shaft must rotate to increment the position data. With this pin open circuit, position data increases with CCW rotation, looking at the shaft. Connecting this pin to Pin T, (DC Return), forces the position to increase with CW rotation, looking at the shaft.

If you want CW increasing counts, you must connect pins R and T at the connector or at the end of a short extension cable. Do not run a long cable pair from these pins and connect these pins at the other end of the cable. This may allow noise to be injected into the Direction Control pin that will affect the position count.

**Pin S: Case GND** – This pin should be used to tie the body of the DuraCoder to chassis ground at the DuraCoder if the unit is not grounded through its mounting. This pin is not to be used as the power supply return. The power supply must be wired to pins T (DC Return) and V (+DC Input).

**Pin T: DC Return** – This pin must be connected the power supply return. The power supply must be wired to pins T (DC Return) and V (+DC Input). This pin cannot be used to tie the body of the DuraCoder to chassis ground.

**Pin U: Latch Control** – The Latch Control input is fully described in the section *Output Update Control*, found on page 8. Briefly here, there are two types of position data update control:

- **Level Sensitive:** The outputs update every 325 microseconds when the pin is open circuit or at a logic 1 voltage level. The outputs will freeze within 25 microseconds when a logic 0 voltage is applied. When the input transitions between a logic 0 and a logic 1, the outputs will take approximately 325 microseconds before they begin to update.

- **Edge Sensitive:** The outputs update within 325 microseconds of a 0→1 or 1→0 transition on the input. The outputs then freeze until another valid transition. Transitions must be at least 325 microseconds apart, which yields a maximum frequency of 1.5KHz with a 50% duty cycle. All of the outputs will be at a logic 0 state on power up until the first valid transition occurs.

**Pin V: +DC Input** – This pin must be connected to the high side of the power supply. The power supply must be wired to pins T (DC Return) and V (+DC Input).
Output States
The Absolute Digital DuraCoder offers both sinking and sourcing outputs. Therefore, these diagnostic instructions list the outputs as being in their active state or inactive state. (Conducting current, or not conducting current.) Table T2.1 below shows the expected output voltages when an output is in its two states. Refer to Part Numbering System, found on page 8 if you need to determine the type of outputs your DuraCoder has.

Table T2.2 Output Voltage States

Over Voltage and Under Voltage Detection
The output driver IC on the DuraCoder has the ability to detect over voltage and under voltage conditions on the power supply and turn off the drivers if either condition occurs. This leaves the outputs in a known state instead of an uncertain state based on the power supply levels. However, this is a feature of the driver IC itself, and does not indicate to the DuraCoder that it is in this state.

Therefore, if the outputs are in their inactive state but the DuraCoder does not give any fault indication, check the power supply voltage and verify that it is within its acceptable range of 10.8 Vdc to 26.4Vdc.
Error Output

The Error output is the same driver type as the position outputs, with an internal pull-up or pull-down resistor. Therefore, the “high” voltage is equal to the voltage that powers the DuraCoder.

The output can sink or source a maximum of 500 milliamperes. It is designed to drive a typical PLC DC input. Figure T2.1 below shows how to wire the output to a typical DC input.

![Figure T2.1 Error Output Wiring](image)

For sinking output units, the output is low during normal operation. For sourcing output units, the output is high for normal operations. The output switches to its inactive state when one of the following conditions occurs:

- Over temperature fault on the output driver IC.
- One or more outputs shorted to ground.
- One or more outputs shorted to the input voltage of the DuraCoder.
- One or more outputs with an open connection or broken wire.

These faults are latched. Once they occur, the DuraCoder will report the error until it is cleared. There are two methods to clear the error.

1) Cycle power to the DuraCoder
2) Pull the Test input (Pin P) low for a minimum of 10 milliseconds and release it.

If the fault condition no longer exists, the Error output will return to its active state and the Status LED on the back of the unit will change from red to green.

Test Input

The Test input is a DC input with an internal pull-up resistor to the supply voltage of the DuraCoder. When the Test input is pulled low for a minimum of 325 microseconds, the DuraCoder is placed in test mode. The unit remains in test mode while the Test input is low. Once the Test input is released, the DuraCoder will return to its normal mode of operation within 325 microseconds.

Normal Operation (Test Pin Open)

During normal operation, the Status LED is in one of three states:

<table>
<thead>
<tr>
<th>Status LED State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>No power to the DuraCoder.</td>
</tr>
<tr>
<td>Green</td>
<td>Operating normally</td>
</tr>
<tr>
<td>Red</td>
<td>A fault condition exists. See the Error Output section above for a list of detectable errors.</td>
</tr>
</tbody>
</table>

Table T2.3 Output Voltage States

If there are no faults, the state of the outputs is determined by the DuraCoder shaft position. If there is an overtemperature fault, all of the outputs are forced into their inactive state. For all other fault conditions, the state of the unaffected outputs is determined by the DuraCoder shaft position.
**Test Input (continued)**

**Test Mode (Test Pin Tied to GND)**

In Test mode, all of the outputs are forced into their active or inactive states. This is accomplished by pulling the Test input low for a minimum of 325 milliseconds. The DuraCoder remembers the last state the outputs were forced into. Once the Test input is released for a minimum of 325 milliseconds and pulled low again, the outputs will switch to their other test state. When the Test input is released for a minimum of 325 milliseconds, the unit exits Test Mode, and the outputs begin to output position data again.

**Testing Sourcing Output DuraCoders**

A pull down resistor or equivalent load is required when testing sourcing outputs. If this load is not present, a voltmeter may read that the output is active when it is in its inactive, high impedance, state due to leakage current through the output.

**High True Output Units**

High True output units have the output at 0 Vdc for a logic “0” and +Vdc for a logic “1”.

➢ If the Test Pin in pulled low when power is applied to the unit, all outputs are set to 0 Vdc. The drivers are not conducting and this is considered a logic “0”.

1) If the Test Pin is high or open during power up, the first time it is pulled low for greater than 325 milliseconds, all outputs are set to the +Vdc voltage. The drivers are conducting and this is considered a logic “1”. If the output voltage is at 0 Vdc, you have a short to ground or a wiring error.

2) Releasing the Test Input for more than 325 milliseconds will take the unit out of test mode and back to normal operation.

3) Pulling the Test Input low for greater than 325 milliseconds will place the unit back into test mode. All of the outputs are now set to 0 Vdc. The drivers are not conducting and this is considered a logic “0”. If the output voltage is at +Vdc, you have a short to +Vdc or a wiring error.

4) Releasing the Test Input for more than 325 milliseconds will take the unit out of test mode and back to normal operation.

Repeating steps 1 through 4 will force the outputs to alternate between their logic “1” and “0” states.

**Low True Output Units**

Low True output units have the output at 0 Vdc for a logic “1” and +Vdc for a logic “0”.

➢ If the Test Pin in pulled low when power is applied to the unit, all outputs are set to the +Vdc voltage. The drivers are conducting and this is considered a logic “0”.

1) If the Test Pin is high or open during power up, the first time it is pulled low for greater than 325 milliseconds, all outputs are set to 0 Vdc. The drivers are not conducting and this is considered a logic “1”. If the output voltage is at +Vdc, you have a short to +Vdc or a wiring error.

2) Releasing the Test Input for more than 325 milliseconds will take the unit out of test mode and back to normal operation.

3) Pulling the Test Input low for greater than 325 milliseconds will place the unit back into test mode. All of the outputs are now set to the +Vdc voltage. The drivers are conducting and this is considered a logic “0”. If the output voltage is at 0 Vdc, you have a short to ground or a wiring error.

4) Releasing the Test Input for more than 325 milliseconds will take the unit out of test mode and back to normal operation.

Repeating steps 1 through 4 will force the outputs to alternate between their logic “1” and “0” states.
Testing Sinking Output DuraCoders

If the unit does not have internal pull up resistors, external pull up resistors or equivalent loads are required when testing sinking outputs. If this load is not present, a voltmeter may read that the output is active when it is in its inactive, high impedance, state due to leakage current through the output.

When the unit has internal pull up resistors, the voltage on the outputs will be equal to +Vdc. When external pull up resistors are used, the pull up voltage on those resistors does not have to be the same as +Vdc. For example, the DuraCoder can be powered by 24 Vdc, while the pull up resistors have 12 Vdc, or 5 Vdc, as their supply voltage. For simplicity in the explanations that follow, “+Vdc” will be used to describe the voltage on the pull up resistors.

High True Output Units

High True output units have the output at 0 Vdc for a logic “0” and +Vdc for a logic “1”.

- If the Test Pin in pulled low when power is applied to the unit, all outputs are set to 0 Vdc. The drivers are conducting and this is considered a logic “0”.

1) If the Test Pin is high or open during power up, the first time it is pulled low for greater than 325 milliseconds, all outputs are set to the +Vdc voltage. The drivers are not conducting and this is considered a logic “1”. If the output voltage is at 0 Vdc, you have a short to ground or a wiring error.

2) Releasing the Test Input for more than 325 milliseconds will take the unit out of test mode and back to normal operation.

3) Pulling the Test Input low for greater than 325 milliseconds will place the unit back into test mode. All of the outputs are now set to 0 Vdc. The drivers are not conducting and this is considered a logic “0”. If the output voltage is at +Vdc, you have a short to ground or a wiring error.

4) Releasing the Test Input for more than 325 milliseconds will take the unit out of test mode and back to normal operation.

Repeating steps 1 through 4 will force the outputs to alternate between their logic “1” and “0” states.

Low True Output Units

Low True output units have the output at 0 Vdc for a logic “1” and +Vdc for a logic “0”.

- If the Test Pin in pulled low when power is applied to the unit, all outputs are set to the +Vdc voltage. The drivers are not conducting and this is considered a logic “0”.

1) If the Test Pin is high or open during power up, the first time it is pulled low for greater than 325 milliseconds, all outputs are set to 0 Vdc. The drivers are conducting and this is considered a logic “1”. If the output voltage is at +Vdc, you have a short to ground or a wiring error.

2) Releasing the Test Input for more than 325 milliseconds will take the unit out of test mode and back to normal operation.

3) Pulling the Test Input low for greater than 325 milliseconds will place the unit back into test mode. All of the outputs are now set to the +Vdc voltage. The drivers are not conducting and this is considered a logic “0”. If the output voltage is at 0 Vdc, you have a short to ground or a wiring error.

4) Releasing the Test Input for more than 325 milliseconds will take the unit out of test mode and back to normal operation.

Repeating steps 1 through 4 will force the outputs to alternate between their logic “1” and “0” states.
Notes
