#### **Module Overview**

The AMCI NX3A1E module is a single resolver input programmable limit switch module that is programmed by and communicates on Ethernet. The functionality of the NX3A1E is similar to the AMCI SLC 500 based 8513 module with the following exceptions.

- 1. This module has a total of 16 real outputs. The 16 virtual outputs are not present.
- 2. The default mode of operation is independent mode, not group mode.
- 3. The NX3A1E does not have any interrupt functionality.
- 4. Transducer Fault Latch has been added to the functionality.
- 5. Resolver Type, either AMCI or Autotech, has been added to the functionality.
- 6. Group mode 6 has been added.
- 7. The offset value has been removed from the setup parameters. Since this module stores its parameters on power down, this parameter is not necessary to maintain absolute position through power down.
- 8. A programmable feature allows the outputs to either be disabled, or to remain enabled, if the network connection is removed. Forced outputs are always disabled when the network connection is removed.
- 9. The outputs are always disabled if the unit is in transducer fault. However, the outputs are <u>not</u> disabled when the PLC is in program mode.
- 10. Up to 16 timed outputs can be programmed into the NX3A1E module.

This unit has sixteen I/O points. Eight of outputs and all sixteen inputs are located on the Nexus module itself, and the remaining eight outputs can be located on an external relay board.

The inputs can be programmed to be used either high true or low true, and provide ANDing functions and group control. The inputs are divided into two groups of eight, and can be used as either sinking or sourcing inputs. The status of the 16 inputs is reported to the PLC over Ethernet.

Each of the outputs has 8 On/Off setpoints, and can be programmed to operate in normal, timed, or pulse mode. The outputs can be ANDed with an input or with a motion detector, and can also be forced ON or OFF from the PLC. The outputs will turn off when there is a transducer fault condition, even if it is a clearable transducer fault. The status of the 16 outputs is reported to the PLC over Ethernet. **Outputs should not be programmed on the fly.** The outputs can either be used independently or grouped together in up to six groups. The groups can be programmed to operate in 1 of 6 modes

- Mode 0: Outputs operating in Mode 0 function normally and are not affected by the input terminal or group channel.
- Mode 1: Outputs operating in Mode 1 are always enabled to turn on at their programmed setpoints. When the group input is activated, the group's position is preset to the group's preset value. The input is ignored until the group control position is reached. The input must transition from 0 to 1 after the group control position is reached.
- Mode 2: Outputs operating in Mode 2 are disabled until the group input is activated, at which time the group's position is preset to the preset value. The outputs will be active until the group control position is reached. The input is ignored until the group control position is reached. The input must transition from 0 to 1 after the group control position is reached.
- Mode 3: Outputs operating in Mode 3 can be active only when the group control input is active. The group channel On/Off points are not used in mode 3.

- Mode 4: Outputs operating in Mode 4 will be active for one cycle only when the group's input transitions from 0 to 1 between the group channel's On and Off points. The cycle ends when either the group channel On or Off point is reached, at which point the outputs turn off
- Mode 5: Outputs operating in Mode 5 will be active for one cycle only when the group's input is active in the range between the group channel's On and Off points. The outputs will be active only when the resolver's shaft is turning, or if the first cycle input is active. The outputs will turn off after there is no change in position for either 504ms or 120ms, depending on how the tachometer response parameter is set. The cycle ends when either the group channel On or Off setpoint is reached, at which point the outputs turn off.
- Mode 6: Mode 6 is similar to mode 5 except that the outputs will be disabled when the group's position data passes through zero.
- **Note 1**: There are two force functions, Force On and Force Off. When a Force On bit is set, the output it represents will be activated, regardless of the output state. When a Force Off bit is set, the output is represents will be turned off, regardless of the output state. The Force Off bit takes priority over the Force On bit.
- **Note 2:** The module can be programmed to operate two ways, either in Independent or Group mode. When used in independent mode, the outputs will only fire when its corresponding input is active. That is, input 1 will control output 1, input 2 will control output 2, etc. To use independent mode without inputs, set the input state to be active low. Also, when in independent mode, the outputs can only be motion ANDed, they cannot be enable ANDed. When group mode is used, the inputs control the groups.
- **Note 3:** The inputs to the NX3A1E have a debounce time of 0ms, and are scanned every 1ms.
- **Note 4:** In group mode, inputs will be acted on only if the position data is scanned between the programmed group channel's On and Off points. If the resolver position data passes through the group channel in less than 1 ms, the input may not be detected.
- **Note 5:** The module contains non-volatile memory. The setup data and On/Off setpoints will be saved on power down. The offset values and On/Off setpoints are stored in a battery backed RAM, so they can be changed often without damaging the module.

#### **Input Registers**

The NX3A1E module reports the resolver position and velocity data, as well as module status and programming errors to the PLC using 20 input registers. These registers will go to zero if the Nexus unit loses power or if the network connection is lost. The input registers have the following function.

Word(s)	Function		
0	Module status		
1 to 4	Position, velocity, output status, and input status		
5	Module setup programming errors		
6 to 13	Group programming errors and group positions		
14 to 16	Output programming errors		
17 to 19	Reserved, equal to zero		

A detailed description of each of the input register's function is shown below.

#### Word 0: Module Status

- Bit 0: set when setup data is invalid (see input register 5 for a detailed description of the error)
- Bit 1: set when group data is invalid (see input registers 6 and 7 for a detailed description of the error)
- Bit 2: set when Limit Switch data is invalid (see input registers 14 to 16 for a detailed description of the error)
- Bit 3: set when Increment / Decrement Output Number is invalid (range 1 to 16). Also set if any of the unused bits are set in the control word are set, if neither the increment or decrement setpoint bits are selected, or if you try to increment or decrement an output that has not yet been programmed.
- Bit 4: set when the Increment / Decrement Setpoint Number is invalid (range 1 to 9, 9 programs all of the on/off setpoints), if you try to increment an on setpoint past the off setpoint or vice versa, or if you try to increment or decrement a setpoint that has not been programmed.
- Bit 5: set when Message Ignored Error, generated by trying to program the module when a programming error exists, or by sending the Apply Preset command when there is a transducer fault.
- Bit 6: set when Module Fault (generated if the NX3A1E fails its power up test) This bit will also be set if there is no reference voltage present.
- Bit 7: set when Transducer Fault. If the fault is clearable, the position data will be updated, the velocity data will be zero, and the outputs will be disabled.
- Bit 8: MD1 bit, set when the transducer's velocity in RPM is within the range programmed into Motion Detector 1.
- Bit 9: MD2 bit, set when the transducer's velocity in RPM is within the range programmed into Motion Detector 2.
- Bit 10: Tachometer Overflow, set when the scaled tachometer value in input register 2 exceeds 32.767.
- Bit 11: Set when the output registers are being used to force the outputs and inputs on and
- Bit 12: Command Error. Set when more than one of the Command bits 1 to 4 are set, if reserved bits 5 to 12 are set during a programming cycle, or if you try to program groups when the module is operating in independent mode. A command error will also be generated if the Transmit bit is set without any other command bits.

- Bit 13: reserved, always equal to zero
- Bit 14: mode status bit, 0 = independent mode, 1 = group mode
- Bit 15: Acknowledge bit. Set when the NX3A1E module sees that the Transmit bit in output register 0 is set.
- Word 1: Machine Position (The position data is reported if there is a clearable transducer fault)
- Word 2: Scaled Resolver Velocity Data (The velocity data will be zero if there is a clearable transducer fault.
- Word 3: Limit Switch Output Status (bit 0 = output 1, bit 1 = output 2 ... bit 15 = output 16)
- Word 4: Input Status (bit 0 = input 1, bit 1 = input 2 ... bit 15 = input 16) (If the input is configured to be active high, than these bits will be on when the input is receiving power. If the input is configured to be active low, than these bits will be on when the input is not receiving power.)
- Word 5: Setup Programming Errors
  - Bit 0: Scale Factor Error. Set if the Scale Factor is outside of the range of 2 to 8192.
  - Bit 1: Preset Value Error. Set if the Preset Value is outside of the range of 0 to (SF-1).
  - Bit 2: reserved, will always be zero.
  - Bit 3: Motion Detect 1 Error. Set if one or both Motion Detector 1 setpoints are outside the range of 0 to 32,767, or if the setpoints are equal but not zero.
  - Bit 4: Motion Detect 2 Error. Set if one or both Motion Detector 2 setpoints are outside the range of 0 to 32,767, or if the setpoints are equal but not zero.
  - Bit 5: Tachometer Scalars Errors. Set if the Tachometer Multiplier, Tachometer Divisor, or Tachometer Decimal Point parameters are outside of their programmable ranges.
  - Bits 6 to 14: Reserved, will always set to zero.
  - Bit 15: Setup Command Word Error. Set if one or more of the reserved bits in the setup command word are set to "1" during a setup programming cycle.
- Word 6: Group Programming Errors
  - Bit 0: Group Offset/Preset Error. Set if the Group Offset/Preset value is outside of the range of 0 to (SF-1)
  - Bit 1: Group Programming Error. Set if the output quantity or operating mode parameter is invalid.
  - Bit 2: Group Channel Setpoint Error. Set when one or both of the group channel setpoints are outside of the range of 0 to (SF-1) of both setpoints are equal but not zero.
  - Bits 3 to 14: Reserved, will always be set to zero.
  - Bit 15: Group Command Word Error. Set when one or more of the reserved bits in the group command word are set to "1" during a group programming cycle.
- Word 7: Group Number with error. If any of the bits 0 to 2 are set in input register 6, than this word will indicate which group, 1 to 6, has the programming error.
- Word 8: Group 1 position data
- Word 9: Group 2 position data
- Word 10: Group 3 position data
- Word 11: Group 4 position data
- Word 12: Group 5 position data
- Word 13: Group 6 position data

# NX3A1E Specifications Rev 0.0

Resolver PLS Ethernet Module

- Word 14: Output Programming Errors
  - Bit 0: On Setpoint Error. Set when a Limit Switch ON Setpoint is outside of the range of 0 to (SF 1). Input registers 15 and 16 will report which output and setpoint have the error.
  - Bit 1: Off Setpoint Error. Set when a Limit Switch OFF Setpoint is outside of the range of 0 to (SF-1) or if the on and off setpoints are equal but not zero. Input registers 15 and 16 will report which output and setpoint have the error.
  - Bit 2: Advance Error. Set when either the On or Off advance values are outside of the range of ±999. Input register 16 will report which output has the error.
  - Bit 3: Timed Output Error. Set when a timed output range is outside of the range of (1 to 9999) or if the on/off setpoints of a timed output are outside of the range of 0 to (SF-1).
  - Bit 4: Reserved, will always be equal to zero.
  - Bit 5: Pulsed Output Error. Set if there is an error with one or more of the pulsed output parameter. The difference between the leading and trailing edge setpoints must be less than ((Pulse Quantity \* On count) + (Pulse Quantity 1)). This bit will also be set if the on/off setpoints of the pulsed outputs are outside of the range of 0 to (SF-1).
  - Bit 6: Output Quantity Programming Error. This bit will be set if you try to program more than two outputs at a time in Output Programming Block word 1, if no outputs are selected in word 1, or if you try to program outputs not assigned to a group.
  - Bit 7: Reserved, will always be equal to zero.
  - Bit 8: Limit Switch Disabled. Set to "1" when the outputs are disabled because the outputs have not been programmed, if there is a transducer fault, or if the outputs have been disabled by the disable output command. The outputs will also be disabled, and this bit set when either the Setup or Group data has been programmed.
  - Bits 9 to 14: Reserved, will always be equal to zero.
  - Bit 15: Limit Switch Command Word Error. Set under the following three conditions
    - 1. Set when one or more of the reserved bits in the output command word are set to "1" during a group programming cycle.
    - 2. Set if you try to use both motion detect ANDing on a single output.
    - 3. When the module is used in group mode, this bit is set if you attempt to program a limit switch that has not been assigned to a group.
- Word 15: Output Number where output programming error occurred, range of 1 to 16.
- Word 16: Setpoint Number where output programming error occurred, range of 1 to 8
- Words 17 to 19: Reserved, set to zero

#### **Output Registers**

The NX3A1E module is programmed through 40 output registers. Because of the amount of data that is be required to totally program the module, and to limit the number of words transferred over Ethernet, five different programming blocks are used to program the module. Output register 0 always has the same function, and the function of registers 1 to 39 will vary depending on the data contained in word 0. Because of this programming method, a maximum of 10 programming cycles will be required to completely program the module. The following table outlines the five programming blocks.

Programming Block	Function		
Setup	Count Direction, Tachometer Response, Module type, Transducer Fault		
	Latch, Transducer Input Type, Scale Factor, Preset Value, Motion Detect		
	Values, and Input Active State.		
Group	Number of outputs assigned to group, group mode, group channel on and off setpoints, group preset/offset value. All six groups are programmed with one cycle.		
Output	Limit switch type, ANDing type, on/off advances, 8 on/off setpoints. Two outputs can be programmed with each programming cycle, requiring 8 programming cycles to program all 16 outputs.		
Increment /	Select increment/decrement type, limit switch to be adjusted, and setpoint to		
Decrement	be adjusted. Only one output can be changed with each programming cycle.		
Force	Force outputs and inputs on or off. Sending this programming block places the module in a "Force Mode" in which any changes to the appropriate output registers will be acted on without a programming cycle.		

Word 0: Control Word (This Command word will be used to program all of the programming blocks. Setting more than one of the bits 0 to 4, or setting bits 5 to 12 during a programming cycle will generate a command error, Input register 0, bit 12)

Bit 0: Apply Preset Value to Machine Position

Bit 1: Program Setup

Bit 2: Program Groups

Bit 3: Program Outputs

Bit 4: Program Increment / Decrement Function

Bit 5: Place Output Registers in Force mode

Bits 6 to 12: Reserved, must be equal to zero

Bit 13: Set to disable all outputs, reset to enable all outputs (This parameter is not saved on power down, and can be set with other command bits.)

Bit 14: Clear Errors

Bit 15: Transmit Bit (When programming the NX3A1E, the Transmit Bit <u>must</u> be set when sending the Control Word to the unit. Do not send the Control Word in one rung or branch and set the transmit bit in another.)

**Note**: If the PLC is powered, and the transmit bit is set when the Nexus unit is powered up, then the Nexus unit will act on any valid data contained in the output registers. If the PLC is powered up with the transmit bit on, then the Nexus unit will ignore any valid data in the output registers.

### Setup Programming Block, Words 1 to 39

**Note**: Programming the Setup Data clears both the Group and Output Programming.

Word 1: Bit level Setup Functions

Bit 0: Count Direction (0 = increasing CW, 1 = increasing CCW)

Bit 1: Tachometer Response (0 = 504ms, 1 = 120ms update time. The update time applies to the tachometer data reported over Ethernet, and the ON/OFF status of the motion detectors.)

Bit 2: Module Type (0 = Independent Mode, 1 = Group Mode)

Bit 3: Reserved, must be set to zero.

Bit 4: Transducer fault latch (0 = fault latched, 1 = fault cleared)

Bit 5: Resolver Type (0 = AMCI, 1 = Autotech, default is AMCI)

Bit 6: Reserved, must be set to zero.

Bit 7: Reset to disable the outputs when there is no network connection. Set to have the outputs remain enabled when there is no network connection. If set, the outputs will turn on and off based on the resolver's position. Please note that forced outputs are always disabled when the network connection is removed, regardless of the state of this bit.

Bits 8 to 15: Reserved, must be equal to zero

Word 2: Scale Factor (2 to 8192)

Word 3: Preset Value (0 to (SF-1))

Word 4: Motion Detect 1 Low RPM (0 to 32,767)

Word 5: Motion Detect 1 High RPM (0 to 32,767)

Word 6: Motion Detect 2 Low RPM (0 to 32,767)

Word 7: Motion Detect 2 High RPM (0 to 32,767)

Word 8: Real Input Active State. Reset if the input is active low, set if the input is active high. (bit 0 = input 1, bit 1 = input 2, ... bit 15 = input 3)

Word 9: Tachometer Multiplier (0 to 1100)

Word 10: Tachometer Divisor (0 to 63, 0 only if Tachometer Multiplier is 0)

Word 11: Tachometer Decimal Point (0 to 3)

Word 12: Reference Voltage Setting Word. This word is valid only when both a test MS-8 connector is present and a jumper strap is installed on JP3 and at power up. The default value is about 7000, which will produce a reference voltage of about 3.09Vrms. This word has a range of 4640 to 8190.

Words 13 to 39: Not used. These words should be "don't cares."

### Group Programming Block, Words 1 to 39

Note: Programming the Group Setup clears the output programming

The setup programming bits of all six groups has the following layout:

Bit(s)	Function
0 to 5	The number of limit switch outputs in the group, range of 1 to 16
6 and 7	Reserved, must be reset to zero
8 to 10	The mode used in the group, range of 0 to 6
11 to 14	Reserved, must be reset to zero
15	set when the group is to be used, reset if the group is to be disabled

Word 1: Group 1setup programming bits

Word 2: Group 1 Channel On Point

Word 3: Group 1 Channel Off Point

Word 4: Group 1 Offset or Preset Value (mode dependent)

Word 5: Group 2 setup programming bits

Word 6: Group 2 Channel On Point

Word 7: Group 2 Channel Off Point

Word 8: Group 2 Offset or Preset Value (mode dependent)

Word 9: Group 3 setup programming bits

Word 10: Group 3 Channel On Point

Word 11: Group 3 Channel Off Point

Word 12: Group 3 Offset or Preset Value (mode dependent)

Word 13: Group 4 setup programming bits

Word 14: Group 4 Channel On Point

Word 15: Group 4 Channel Off Point

Word 16: Group 4 Offset or Preset Value (mode dependent)

Word 17: Group 5 setup programming bits

Word 18: Group 5 Channel On Point

Word 19: Group 5 Channel Off Point

Word 20: Group 5 Offset or Preset Value (mode dependent)

Word 21: Group 6 setup programming bits

Word 22: Group 6 Channel On Point

Word 23: Group 6 Channel Off Point

Word 24: Group 6 Offset or Preset Value (mode dependent)

Words 25 to 39: Not used. These words should be "don't cares."

# Output Programming Block, Words 1 to 39

Word 1: Outputs programmed. This word controls which two outputs are programmed in output registers 2 to 39. Each bit in this word corresponds to an output, that is bit 0 =output 1, bit  $1 = \text{output } 2, \dots \text{ bit } 15 = \text{output } 16$ . Any two bits can be set during an output programming cycle. The output assigned to the least significant bit of the two will be programmed in words 2 through 20 and is called the Lower Output. The most significant bit of the two will be programmed in words 21 through 39 and is called the Upper Output. If only one bit is set, only registers 2 through 20 will be used, and the data in words 21 through 39 will be ignored. Setting more than two bits will generate an Output Quantity Error, which is indicated by input word 14, bit 6. Any errors in the output programming data will cause even valid changes to be ignored.

**OUTPUT SETUP WORDS**: The first word of each of the two output programming blocks, words 2 and 21, contain the Output Setup Word. These words define the type of output (normal, timed, or pulsed) and if any ANDing will be used. The description of these output words is shown below.

bits  $0 \rightarrow 1$ : output type

Bit 1	Bit 0	Function
0	0	Output not used
0	1	Pulse Output
1	0	Timed Output
		(Starts timing only after the input is active. This does
		not include the group mode enable bit.)
1	1	Normal Output

bits  $2 \rightarrow 12$ : not used

bits  $13 \rightarrow 14$ : motion ANDing control bits

Bit 14	Bit 13	Function
0	0	No Motion ANDing
0	1	Motion ANDing 1
1	0	Motion ANDing 2
1	1	Reserved for future use

Note: The operation of motion ANDing function includes the Low Value setpoint, but not the High Value setpoint. That is, an output that is motion ANDed will turn on at the Low Value, and off when the High Value setpoint is reached.

bit 15: In group mode only, this bit is set for Output Enable ANDing (by input) and reset for no ANDing. In group mode, enable ANDed timed outputs start timing regardless of the state of the enable input. This bit is a "don't care" in independent mode.

- Word 2: Lower output Setup Word (see description on the previous page)
- Word 3: Lower output ON advance/retard value, entered in 0.1ms increments. Range of +99.9ms.
- Word 4: Lower output OFF advance/retard value, entered in 0.1ms increments. Range of +99.9ms.
- Word 5: Lower Output, Normal Output On setpoint 1

Timed Output On Setpoint 1

Pulsed Output On position of leading edge of first pulse

Word 6: Lower Output, Normal Output Off setpoint 1

Timed Output Off setpoint 1

Pulsed Output Off position of trailing edge of final pulse

Word 7: Lower Output, Normal Output On setpoint 2

Timed Output, length of time in ms, range of 1 to 9999ms

Pulsed Output, total number of pulses

Word 8: Lower Output, Normal Output, Output 1 Off setpoint 2

Pulsed Output, the duration of each pulse (the ON time)

- Word 9: Lower Output, On setpoint 3
- Word 10: Lower Output, Off setpoint 3
- Word 11: Lower Output, On setpoint 4
- Word 12: Lower Output, Off setpoint 4
- Word 13: Lower Output, On setpoint 5
- Word 14: Lower Output, Off setpoint 5
- Word 15: Lower Output, On setpoint 6
- Word 16: Lower Output, Off setpoint 6
- Word 17: Lower Output, On setpoint 7
- Word 18: Lower Output, Off setpoint 7
- Word 19: Lower Output, On setpoint 8
- Word 20: Lower Output, Off setpoint 8
- Word 21: Upper output Setup Word (see description on the previous page)
- Word 22: Upper output ON advance/retard value, entered in 0.1ms increments. Range of +99.9ms.
- Word 23: Upper output OFF advance/retard value, entered in 0.1ms increments. Range of +99.9ms.
- Word 24: Upper Output, Normal Output On setpoint 1

Timed Output On Setpoint 1

Pulsed Output On position of leading edge of first pulse

Word 25: Upper Output, Normal Output Off setpoint 1

Timed Output Off setpoint 1

Pulsed Output Off position of trailing edge of final pulse

Word 26: Upper Output, Normal Output On setpoint 2

Timed Output, length of time in ms, range of 1 to 9999ms

Pulsed Output, total number of pulses

Word 27: Upper Output, Normal Output, Output 1 Off setpoint 2

Pulsed Output, the duration of each pulse (the ON time)

- Word 28: Upper Output, On setpoint 3
- Word 29: Upper Output, Off setpoint 3
- Word 30: Upper Output, On setpoint 4
- Word 31: Upper Output, Off setpoint 4
- Word 32: Upper Output, On setpoint 5

# NX3A1E Specifications Rev 0.0

#### Resolver PLS Ethernet Module

- Word 33: Upper Output, Off setpoint 5 Word 34: Upper Output, On setpoint 6
- Word 35: Upper Output, Off setpoint 6
- Word 36: Upper Output, On setpoint 7
- Word 37: Upper Output, Off setpoint 7
- Word 38: Upper Output, On setpoint 8
- Word 39: Upper Output, Off setpoint 8
- Note 1: Output words 8 to 39 are "don't cares" if the output is being programmed as a timed output.
- Note 2: Output words 9 to 39 are "don't cares" if the output is being programmed as a pulsed output.
- Note 3: Unused normal on/off setpoints should be set to zero.

## **Increment / Decrement Programming Block, Words 1 to 39**

Word 1: control bits

Bit 0: set to change on setpoint Bit 1: set to change off setpoint

Bit 2: reset to increment setpoint, set to decrement setpoint

Bits 3 to 15: reserved, must be reset to zero

Word 2: Increment/Decrement Limit Switch Number (range 1 to 16)

Word 3: Increment/Decrement Setpoint Number (range 1 to 9) (if the value equals 9, than all of the on/off setpoints will be incremented or decremented.)

Words 4 to 39: Not used. These words should be "don't cares.

**Note**: The Increment/Decrement function cannot be used on outputs that have not been programmed.

#### Force Function Programming Block, Words 1 to 39

The force function works differently than the other programming blocks. Once the output registers are in force mode, any changes to the data will be acted on immediately. That is it will not be necessary to use a programming cycle to change the force values. Input register 0, bit 11 will be set to indicate that the module is in force mode.

Word 1: Force Outputs On

Word 2: Force Outputs Off

Word 3: Force Inputs On

Word 4: Force Inputs Off

Words 5 to 39: Not used, should be considered "don't cares."

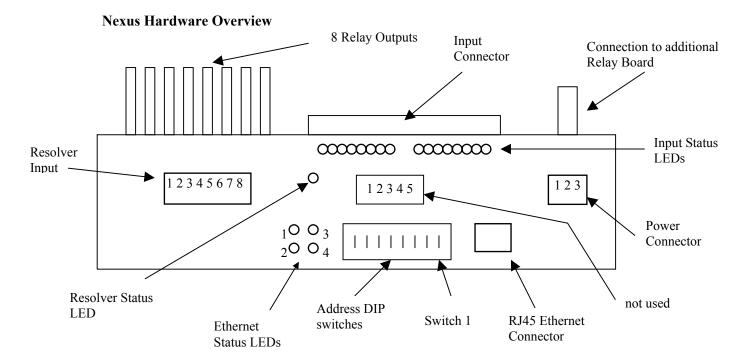

Note 1: Force Off takes priority over Force On.

Note 2: It is not necessary to program the outputs before the force will take affect.

Note 3: Cycling power to the unit takes the module out of force mode.

Note 4: Transmitting any of the other programming blocks to the Nexus takes the unit out of force mode.

Note 5: Outputs that have been forced on will remain on even if the unit is in transducer fault.

**Dimension**: Length = 10 inches

Width = 4.5 inches

Height = 4.75 inches (including relays)

#### Notes:

- 1. The ribbon cable from the NX3A1E must be plugged into the CN2 connector of the additional relay board.
- 2. The additional relay board does not require any external power connections
- 3. If they exist, the inputs on the relay board do not have any function.

#### **Resolver Connector**

Pin Number	Single Turn Function	
1	R1	
2	R2	
3	Shields	
4	S1 & S2	
5	S4	
6	S3	
7	no connection	
8	no connection	

#### **Resolver Status LED**

LED Pattern	Function
solid green	Resolver OK
flashing green	Clearable Transducer Fault
flashing red	Non Clearable Transducer Fault
solid red	Module Fault
Alternating Red	Nexus is not communicating
and Green	with network interface card

#### **Input Status LEDs**

The Nexus unit has 16 inputs that are divided into two groups, each with its own common. Depending on what is connected to the common, the inputs can be either sinking or sourcing.

Common Connection	Input Type LED color when input active	
Ground	sinking	Red
+DC voltage	sourcing	Green

#### **Input Function**

In Independent Mode, each input is anded with each output. That is, input 1 is anded with output 1, input 2 is anded with output 2 ... input 16 is anded with output 16. In group mode, the inputs have the following functions.

Input	Function
1	Group 1 Control
2	Group 2 Control
3	Group 3 Control
4	Group 4 Control
5	Group 5 Control
6	Group 6 Control
7	Limit Switch Enable Input
8	First Cycle Input
9 to 16	not used in group mode

## **Power Requirements**

#### **Power Connector**

Pin	Function
1	10 to 30Vdc
2	DC Common
3	Chassis Ground

The Nexus Module requires exactly 200mA @24Vdc to operate. If the reference voltage pins are shorted together, the unit will draw 300mA @24Vdc.

The Chassis Ground pin is connected to the NX3A1E's body and must be connected to your Earth Ground bus for proper module operation.

Resolver PLS Ethernet Module

Even though the unit will operate within a voltage range of 10 to 30Vdc, it is recommended that the unit be powered with a supply that is within the operating range of the relays. The Opto 22 ODC24 relays have an operating range of 18 to 30Vdc.

## **Throughput Time**

The NX3A1E has a typical throughput time of  $100\mu$ s from input to output. The maximum throughput time from input to output is  $200\mu$ s. Also, the minimum on and off time for an output is  $200\mu$ s.

#### Power Up Delay

There is an eight second delay between power up and when the NX2A4E begins to communicate with the network.

#### **Ethernet Address Selection**

The NX2A4E uses an IP address of 192.168.000.XXX where "XXX" can be any number between 1 and 254. Eight dip switches on the NX2A4E are used to set the "XXX" portion of the address. Switch 8, the left most switch, is the least significant bit and switch 1, the right most switch, is the most significant bit. The address is programmed using the following procedure.

- 1. Determine the address of the NX2A4E. It can be any unused address between 1 and 254.
- 2. Convert the address to a binary number. A value of 50 will be 0011 0010.
- 3. Enter the address on the dip switches. Continuing the above example, switches 8, 6, 5, 2 and 1 will be off (down) and switches 7, 4, and 3 will be on (up).

#### **Ethernet Status LEDs**

The following table describes the function of the four network status LEDs.

LED	Name	LED Pattern	Function
Number			
		Steady Off	The module has no power or on IP address has been assigned.
		Steady Green	The module has at least one established Ethernet/IP connection.
1	Network	Flashing Green	There are no Ethernet/IP connections established to the module
	Status	Flashing Red	One or more of the connections in which this module is
			the target has timed out
		Steady Red	The module has detected that its IP address is already in use
		Flashing Green/Red	The module is performing a power on self test
		Steady Off	No Power.
		Steady Green	The module is operating correctly.
2	Module	Flashing Green	The module has not been initialized.
	Status	Flashing Red	A minor recoverable fault has been detected.
		Steady Red	A major internal error has been detected.
		Flashing Green/Red	The module is performing a power on self test.
3	Activity		This LED flashes green each time a packet is received or
	LED		transmitted
4	Link		This LED indicates that the module is connected to an Ethernet
			network

## Setup Example

## AMCI NX2A4E to Rockwell Automation 1756-ENET/B module

- 1. With power removed, use the dip switches to set the address of the NX2A4E.
- 2. Open an existing or create a new ControlLogix program.
- 3. From the project tree, right click on I/O configuration and select New Module.
- 4. From the Module Type list that appears, select 1756-ENET/B, the 1756 Ethernet Bridge module
- 5. Type a name for the Bridge module, which must begin with a letter, in the Name field.
- 6. Enter the slot number where the 1756-ENET/B module is located in the ControlLogix rack.
- 7. In the Address/Host Name field, select the IP Address and enter the address 192.168.000.XXX where XXX can be a unique number between 1 and 254.
- 8. Click the Finish button.
- 9. From the project tree, right click on the 1756-ENET/B module and select New Module.
- 10. Select ETHERNET-MODULE Generic Ethernet Module from the list that appears and click on OK.
- 11. In the module properties that appear, enter the following parameters.

Name: **Your Choice** (must begin with a letter) Comm Format: **Data-INT** (must be Data-INT)

IP Address: 192.168.000.XXX where XXX is the number entered on the DIP switches

	Assembly Instance	Size
Input	100	20
Output	150	40
Configuration	110	0

- 12. Click on Next.
- 13. Select the RPI time, minimum = 3ms.
- 14. Click on Finish.
- 15. Save and download the program to the ControlLogix rack.
- 16. While online with the PLC, right click on the Ethernet Bridge module and select Properties.
- 17. Click on the Port Configuration tab and modify the following fields.

Enable Bootp: **Unselected** (This will allow the data to be manually entered in the IP address and Domain Name fields.)

IP Address: 192.168.000.XXX (must be the same as step 7 above)

Subnet Mask: 255.255.255.0

The Gateway Address, Domain Name, Primary DNS Server Address, and Secondary DNS Server Addresses all remain unchanged.

#### **Revision History:**

Version 0.0 was released on 9/1/04 and was the initial release of the specifications.

File: NX3A1E\_rev\_0.0

Date: 9/7/04
